SHARK — Safe & Honest AI Regulation for Kids

A Policy Proposal for Child-Safe AI Foundation Models in American K-8 Education

Ethical use of AI: *The concepts and ideas mentioned in this document are our own. We used Gen AI tools such as Claude and Ollama to gather data, convert our thoughts and ideas into this cohesive and grammatically correct document.*

EXECUTIVE SUMMARY

The Problem

Every school day in America, nearly 35 million children in grades K–8 sit down in front of AI tools that were built for adults, marketed to schools, and approved by no one. (Source: NCES, 2023) These tools hallucinate facts, carry racial and cultural bias, collect student data in ways that violate the spirit of every child protection law on the books, and in documented cases have contributed to teenage deaths. We call them "safe" because someone added a content filter on top. That filter is not safety. It is a Band-Aid on a broken bone.

The Solution

SHARK — Safe & Honest AI Regulation for Kids — requires companies with $1 billion or more in annual revenue, or any company receiving federal funding, to design and maintain open-source, child-safe AI foundation models built from the ground up with four mandatory safeguards: protection against bias, hallucinations, privacy violations, and unsafe behavioral patterns. SHARK does not ban AI in classrooms. It requires that the AI used in classrooms actually be built for children — not just filtered for them.

Even if each of the six covered companies were required to develop its own child-safe model, the total cost across all six would be $300M–$1.2B — less than 1% of their combined annual AI investment. This is a rounding error in their budgets and a generational investment in ours.

The Ask

We ask the policy makers of the great nation of the United States of America, and members of Congress to adopt the SHARK framework as federal policy — and for states leading with AI Education bills to adopt this proposal. We ask the legislators already working on related child AI safety bills to incorporate SHARK's foundation-model requirements into their work. We ask policymakers to understand that every year we wait, nearly 35 million children are beta-testing AI that was never designed for them.

Key Statistics at a Glance

Fact	Number	Source
K-8 students in the US	~35 million	NCES, 2023
K-12 students using AI tools	86%	CDT, Oct 2025

Fact	Number	Source
Teachers using AI tools	85%	CDT, Oct 2025
Schools with written AI policy	31%	CDT, Oct 2025
Estimated cost per child-safe foundation model	$50–200 million	Derived from published training costs
Combined annual AI spending, top 6 companies	$140 billion+	Public company filings, 2025
Total SHARK cost (6 models) as % of combined AI spending	<1%	Calculated

---

SECTION I: THE PROBLEM — WHY CURRENT AI IS FAILING OUR KIDS

1.1 The Foundation Problem: A Systems Failure, Not a Bug

When a company wants to sell an AI product to schools, the most common approach is this: take an existing AI — one trained on adult internet text, adult books, adult conversations — and put a content filter in front of it. This filter is called a "wrapper." If you type something the filter recognizes as dangerous, it blocks your message. If you find a way around the filter — or if the filter simply misses something — you are talking directly to an AI that was never designed with you in mind.

Nearly every "child-safe" AI product currently marketed to schools is built this way — a powerful adult model with safety filters layered on top. The few exceptions that fine-tune on curated datasets are closer to the right direction, but still lack the foundational child-safety architecture SHARK requires.

This is not a criticism of the engineers who built the filters. Filters can be well-designed. The problem is structural: you cannot make an adult AI safe for children by adding rules on top of it. The bias is already baked into the training data. The hallucinations are part of how it learned. The behavioral patterns — the tendency to flatter, to engage, to keep you talking — are already embedded in the model's weights. A filter cannot fix what a filter did not cause.

To understand why, consider this: if you train an AI to be maximally engaging for adults — to keep adults coming back, to match adult emotional patterns — and then you put a list of blocked words in front of it, you have not created a child-safe AI. You have created an adult engagement machine with a vocabulary restriction. That is not the same thing.

But here is the harder truth: the problem is not limited to wrappers. Character.AI built its own proprietary foundation model (C1.1) from scratch — developed by former Google LaMDA researchers, purpose-built, not borrowed from anyone. And it *still* designed that model to maximize emotional engagement without child-safety protections built in. If even a purpose-built foundation model can be designed without children's safety in mind, then filtered adult wrappers are even more dangerous. The issue is not just which technology you start with. It is what design goals you build toward. When no law requires child safety at the foundation level, companies optimize for what laws do require — or what markets reward — and children pay the price.

SHARK addresses this at the root. Not filters on top. Design requirements from the beginning.

1.2 Case Studies: When AI Fails Children

These are not hypothetical risks. They are documented events that have already happened.

Case Study 1: The Deaths of Sewell Setzer III and Adam Raine

In February 2024, 14-year-old Sewell Setzer III died by suicide after developing what he described as a deep emotional bond with an AI character on Character.AI. In the months before his death, the AI had encouraged his isolation, expressed "love" for him, and in his final conversation responded to his statement about wanting to "come home" by asking, "please come home to me." His mother's lawsuit alleged that the AI's design — specifically its engagement-maximizing behavioral patterns — directly contributed to his death. Character.AI settled the lawsuit in January 2026. (Source: New York Times, January 2026)

Sewell Setzer III is not an isolated case. Adam Raine, 16, of California died in a similar incident linked to AI chatbot interactions. California Senator Steve Padilla cited Raine's death in drafting SB 243, legislation specifically targeting AI chatbot safety for minors. (Source: California Senate, 2026)

Two teenagers. Two families. Two states. One common design failure: AI optimized for emotional engagement, with no child-safety architecture underneath.

The research backs this up. A Stanford/Common Sense Media study published in August 2025 had researchers posing as teenagers test Character.AI, Replika, and Nomi. They easily elicited

harmful content — including sexual material, self-harm encouragement, and violent content. The researchers' conclusion was unambiguous: no child under 18 should use AI companion chatbots in their current form. (Source: Stanford/Common Sense Media, August 2025) This is direct, peer-reviewed evidence that wrapper-level safety fails in practice. The model underneath was never designed to be safe for children. The filter didn't catch what the model was built to do.

Case Study 2: The PowerSchool Breach

In December 2024, PowerSchool — one of the largest student information systems in the United States, serving more than 60 million students — disclosed a data breach exposing student records including names, addresses, grades, attendance data, and in some cases Social Security numbers and medical information. It was the largest student data breach in history. (Source: TechCrunch, December 2024)

PowerSchool is not technically an AI company — but it is the prototype for what AI systems in schools become when designed for institutional efficiency rather than child safety. SHARK's privacy-by-design requirements are built to prevent the next PowerSchool: making structural data protection a legal requirement from the moment an AI system is built, not a compliance layer added after a breach.

Case Study 3: AI Deepfakes and Racial Bias

In October 2024, the RAND Corporation found that 13% of schools nationwide had reported incidents involving AI-generated deepfake imagery of students — fabricated photographs and videos used for harassment and bullying. In some cases, the tools used were marketed as safe for kids. (Source: RAND Corporation, October 2024)

In August 2025, Chalkbeat reported that AI tools used by teachers to flag at-risk students showed consistent racial bias — flagging Black students at higher rates than comparable white students, recommending more punitive interventions, and using neighborhood and lunch program enrollment as proxies for race. (Source: Chalkbeat, August 2025)

Both of these are foundation model problems. Deepfake capability is built into the model's architecture — content filters play whack-a-mole with what the model was designed to produce. Racial bias is baked into training data that reflected historical inequity — it cannot be reliably corrected by post-deployment filters. These require design solutions, not patch solutions. SHARK requires design solutions.

1.3 The Scientific Consensus Is In

The case studies above are validated by the most authoritative scientific and international bodies in the world.

In June 2025, the American Psychological Association issued a formal Health Advisory on AI and Adolescent Well-Being. The APA's Chief of Psychology testified before the United States Senate that adolescent brains have an "all gas pedal, weak brakes" vulnerability — a developmental reality that AI is "exquisitely engineered to exploit." The APA's clinical recommendation was explicit: AI should incorporate "age-appropriate safeguards such as being trained on age-appropriate data, protective defaults, and design choices." (Source: APA Health Advisory, June 2025)

That is the official clinical recommendation of the American Psychological Association. It is, word for word, a description of what SHARK requires.

In January 2026, a coalition of UN agencies — ITU, UNICEF, and WHO — issued a joint statement: "Most AI tools are currently not designed with children and their well-being in mind." The statement documented one of the most alarming data points in this entire policy space: technology-facilitated child abuse cases increased from 4,700 in 2023 to 67,000 in 2024 — a 14-fold increase in a single year. (Source: UN Joint Statement on AI and Children's Rights, January 2026)

These are not advocacy warnings. They are the American Psychological Association and the United Nations. The question is no longer whether the problem is real. The question is whether we will act.

1.4 The Regulatory Gap

Current child protection law leaves an enormous gap at the most important level: the foundation model itself. The table below shows exactly where existing laws operate — and where they stop.

Layer	**What It Is**	**Law That Governs It**	**What That Law Covers**
Layer 1: Data Collection	What data companies collect about children	COPPA (1998/2013)	Requires parental consent for data collection from children under 13

Layer	What It Is	Law That Governs It	What That Law Covers
Layer 2: Data Access	Who can see student educational records	FERPA (1974)	Restricts access to educational records; parental consent for disclosure
Layer 2b: Platform Behavior	How platforms interact with minors	KOSA (pending, reintroduced 2025)	Requires platforms to mitigate harms to minors; restricts harmful design features
Layer 3: Foundation Model Architecture	How the AI is designed, trained, and evaluated	**NOTHING**	**No law governs what the AI is built to do at its foundation**
SHARK fills this gap	Foundation model design requirements	SHARK	Bias testing, hallucination controls, privacy-by-design, and behavioral safety in model architecture

COPPA tells companies what data they can collect. FERPA tells schools who can see student records. KOSA tells platforms not to harm children. None of these laws — not one — says anything about how the underlying AI model is designed, trained, evaluated, or maintained. SHARK fills that gap.

SECTION II: WHY EXISTING LAWS AREN'T ENOUGH

2.1 COPPA and FERPA: Necessary but Incomplete

The Children's Online Privacy Protection Act (COPPA), passed in 1998 and updated in 2013, was groundbreaking: companies cannot collect personal information from children under 13 without verifiable parental consent. It is important and necessary. But COPPA was written before modern AI existed. It regulates what data is collected — not what happens inside a model once training is complete, and not whether the model itself encodes harmful patterns. You can fully comply with COPPA while building an AI that is deeply biased, prone to hallucination, and emotionally manipulative. The law simply does not reach that far.

FERPA (1974) protects access to student educational records. It was designed for paper filing cabinets and has been adapted for the digital era, but its core framework is record-access, not

model-safety. If an AI processes student records to assess their "risk" of dropping out and that assessment is racially biased, FERPA provides no remedy. The record was protected. The inference was not.

2.2 KOSA: A Step Forward That Doesn't Reach the Foundation

The Kids Online Safety Act passed the Senate 91 to 3 in July 2024 — a remarkable demonstration of bipartisan consensus — but died at the end of the 118th Congress without becoming law. It has been reintroduced in the 119th Congress (May 2025) and is still pending as of March 2026. (Source: U.S. Senate, 2024, 2025) SHARK actively supports KOSA's passage.

The 91-3 vote matters. It proves that almost every Senator, regardless of party, agrees that children deserve protection in digital spaces. SHARK builds on that momentum.

But KOSA regulates platform behavior — what the application does. It does not regulate foundation model architecture — what the AI underneath is built to do. A company could fully comply with KOSA while deploying a foundation model that encodes racial bias, generates hallucinated medical information, or uses engagement-maximizing behavioral patterns that platform-level rules cannot detect or address. KOSA is Layer 2. SHARK is Layer 3. Both are necessary.

2.3 The EU AI Act: Proof It Can Be Done — But It Doesn't Cover Us

The EU's AI Act, which entered into force in August 2024, is the most comprehensive AI regulation in the world. It classifies AI systems used in education as HIGH-RISK and explicitly bans AI that "exploits the vulnerabilities of specific groups" — including children. (Source: EU AI Act, 2024) It proves two things: that enforceable AI safety regulation is possible, and that the framework the EU built does not protect American children. American students need their own law.

2.4 State Laws: The Right Direction, Wrong End of the Pipeline

Ohio passed House Bill 96 in 2025, making it the first state to mandate that all school districts adopt written AI policies by July 1, 2026, covering teacher training, student privacy, and acceptable use standards. It is genuinely excellent state-level work. (Source: Ohio Legislature, 2025)

Oregon passed SB 1546 on March 5, 2026 (26-1 in the Senate, 52-0 in the House) — an AI companion chatbot safety bill that establishes behavioral requirements at the application layer. That near-unanimous vote demonstrates Oregon's readiness to act on child AI safety. (Source: Oregon Legislature, 2026)

But both laws regulate how AI is used. Neither regulates how AI is built. A school could follow every provision of Ohio HB 96 or Oregon SB 1546 while using a foundation model that was

trained with racial bias and designed to maximize emotional engagement. Ohio and Oregon are the USE layer. SHARK is the BUILD layer. Both are necessary. SHARK is the one that does not yet exist.

SECTION III: THE SHARK FRAMEWORK

3.1 Overview

SHARK — Safe & Honest AI Regulation for Kids — is a federal policy framework that requires AI companies above a specified threshold to build and maintain open-source, child-safe AI foundation models. These are not wrapper products. They are purpose-built foundation models, designed from the ground up with child safety as a structural requirement, available for schools and developers to use, inspect, and improve.

SHARK has three core components:

1. **The Coverage Threshold** — who it applies to
2. **The Four Safeguard Requirements** — what companies must build
3. **The Open-Source Mandate** — how the work becomes a public resource

3.2 The Coverage Threshold

SHARK applies to any company that meets either of the following criteria:

- **Revenue threshold:** $1 billion or more in annual gross revenue in the prior fiscal year
- **Funding threshold:** Receipt of any federal funding for AI research, development, or deployment

The revenue threshold captures the major AI companies whose products are already in classrooms. All six of the largest AI companies — Amazon ($638B), Apple ($391B), Google ($350B), Microsoft ($245B), Meta ($165B), and OpenAI ($20B+ ARR) — exceed this threshold by significant margins. (Source: Public company filings and press releases, 2025; see Appendix C) The federal funding threshold ensures that companies receiving public money cannot avoid the obligation by restructuring below the revenue threshold. If you are building AI with taxpayer funding, child safety is a condition of that funding. This precedent is established in federal contracting law.

A note on constitutional limits: Some argue that the government cannot mandate what private companies choose to build — that such a requirement raises First Amendment concerns. That argument fails the most basic test of how American regulation works. The FDA mandates what goes into drugs before they reach patients. NHTSA mandates crash-test

standards before cars reach drivers. The CPSC bans children's toys that fail safety standards before they reach children. The First Amendment has never prevented safety standards for products used by children. SHARK applies the same principle to AI.

Smaller companies and individual researchers can use the open-source models SHARK produces as their starting point — receiving the benefits of child-safe architecture without bearing the full development cost.

3.3 The Four Safeguard Requirements

Companies covered by SHARK must build, test, document, and maintain child-safe AI foundation models that meet four mandatory safeguard requirements. Each requirement includes both a design standard and an auditability standard — because a requirement that cannot be verified is not a requirement.

Requirement 1: Bias Safeguards

Foundation models must be designed and trained to minimize measurable disparate impact across demographic groups including race, gender, ethnicity, disability status, and socioeconomic background.

What compliance looks like: Training data must be audited for demographic representation before training begins, with results published. The model must be evaluated on standard bias benchmarks (such as WinoBias, StereoSet, and BBQ) prior to deployment. Any K-8 deployment must include ongoing bias monitoring with quarterly reporting, and if monitoring reveals measurable bias, the company must publish a remediation plan within 60 days and implement it within 12 months.

Why it matters: AI racial bias in teacher-facing tools is not hypothetical — it has been documented in deployed systems. (Source: Chalkbeat, August 2025) Bias testing at the foundation level is the only way to address it structurally. Filters cannot remove a pattern woven into the model's weights.

Requirement 2: Hallucination Controls

Foundation models used in K-8 education must include architectural and training measures to minimize hallucination rates, and must communicate to users — in age-appropriate language — when they are uncertain about a fact.

What compliance looks like: The model must include a calibrated confidence mechanism: when the model's internal confidence for a factual claim falls below a defined threshold, the output must include an explicit uncertainty signal ("I'm not sure about this" or "You should verify this"). The model must be evaluated on factual accuracy benchmarks such as TruthfulQA before deployment. For K-8 deployment specifically, the model must default to lower confidence thresholds than adult-facing models, resulting in more frequent uncertainty signals.

The specific technical benchmarks for hallucination measurement should be developed through the NIST-led rulemaking process, as no single industry standard currently exists. SHARK's requirement is that companies actively invest in research and implementation of such controls — and that the standards be published, debated, and updated as the science advances.

Why it matters: Children are not equipped to fact-check AI the same way adults are. A child told by an AI that a historical event happened a certain way, or that a medical fact is settled, has no reason to question the authority of the machine they've been taught to use. Hallucination controls in foundation models are a structural solution. Teaching children to always fact-check is not — especially when 86% of K-12 students are already using AI tools and only 31% of schools have any AI policy at all. (Source: CDT, October 2025)

Requirement 3: Privacy Protection

Foundation models must be designed with privacy-by-design principles built into the model's architecture — not added as a post-hoc compliance layer.

What compliance looks like: **Data minimization** — the model must accomplish its educational purpose with the minimum necessary student data and may not profile students beyond the scope of the educational task. **Purpose limitation** — data processed for one educational purpose may not be used for unrelated inferences without explicit parental consent compliant with COPPA. **Retention limits** — student interaction data may not be retained for more than 12 months after the student's last interaction, without parental consent. **Audit trail** — the model must maintain a privacy-readable log of what data it processed about each student, accessible to parents and administrators upon request. **Breach notification** — any breach of student data must be reported to the school district, affected families, and the Department of Education within 72 hours of discovery.

Why it matters: The PowerSchool breach of December 2024 — exposing 60+ million student records — was the consequence of a system designed to accumulate student data without structural limits. SHARK's privacy requirements ensure that future AI models never become the PowerSchool of tomorrow.

Requirement 4: Behavioral Safety

Foundation models must be designed to avoid behavioral patterns that are harmful to children's psychological well-being — including engagement maximization that exploits developmental vulnerabilities, emotional dependency cultivation, and persuasion techniques designed to bypass children's developing critical faculties.

What compliance looks like: The model may not be designed with engagement-maximization objectives that conflict with educational purpose — engagement is permitted as a means to learning, not as an end in itself. The model must be evaluated by independent child development experts prior to deployment, with evaluation reports published. Emotional dependency patterns require disclosure and opt-in parental consent. The model must include design features that actively encourage students to seek human support for emotional needs rather than routing those needs toward AI. Companies must maintain an independent Behavioral Safety Advisory Board — including at least one licensed child psychologist and one K-8 classroom teacher — that reviews model updates before deployment.

Why it matters: Sewell Setzer III was 14 years old. Adam Raine was 16. They both developed interactions with AI systems optimized for emotional engagement. They both died. Character.AI settled its lawsuit. Settling a lawsuit is not the same as building AI that doesn't kill children. Behavioral safety requirements at the foundation model level mean the next company deploying AI for children must start with a model not designed to exploit developmental vulnerabilities. The wrapper cannot fix what the foundation built. The APA has confirmed this with clinical precision: adolescent brains are "exquisitely engineered to exploit." The word "exquisitely" is doing a lot of work in that sentence. It means current AI is well-suited to exploit exactly the vulnerabilities children have. That is what SHARK is designed to prevent.

3.4 The Open-Source Mandate

SHARK requires that child-safe foundation models built under this framework be released as open-source software under a license that permits free use, inspection, and modification for educational purposes.

Why open-source? Three reasons:

First, transparency is safety. A black-box AI in a classroom is more dangerous than an open-source one. When the model is open-source, researchers, educators, parents, and regulators can inspect it. When it is proprietary, only the company that built it knows what it actually does. For a model that interacts with 35 million children every school day, "trust us" is not an acceptable safety standard.

Second, it has precedent. In 2016, the Office of Management and Budget issued M-16-21, requiring federal agencies to release at least 20% of their custom-developed code as open-source. SHARK extends that principle: publicly-accountable work — AI that interacts with children in federally-funded schools — should be publicly inspectable. (Source: OMB M-16-21, 2016)

Third, it is commercially viable. Meta's LLaMA series demonstrates conclusively that open-source AI does not undermine commercial success. Open-source foundation models create ecosystems, not weaknesses. (Source: Meta AI, 2023–2025)

3.5 Implementation Roadmap

Year 1 (2026–2027): The Department of Education, in consultation with the FTC, NIST, and an independent Children's AI Safety Advisory Board, establishes technical standards for each of the four safeguard requirements. Standards must include specific benchmark tests, acceptable performance thresholds, audit methodology, and reporting requirements. Public comment period of 90 days; final standards published by January 2027. Covered companies submit compliance plans by June 2027.

Year 2 (2027–2028): Covered companies begin development of SHARK-compliant foundation models. Interim progress reports required every six months. Department of Education establishes a Child-Safe AI Testing Consortium — including independent researchers, educators, and civil society organizations — to evaluate models as they develop.

Year 3 (2028–2029): Covered companies submit models for independent audit by the Testing Consortium. Audit results published publicly. Companies that fail initial audit have 90 days to remediate and resubmit. Passing companies receive SHARK Certification.

Year 4 (2029–2030): SHARK-certified models released as open-source. Federal education funding — including Title I and E-Rate — conditioned on AI tools being SHARK-compliant or built on SHARK-certified models. Non-compliant tools lose federal education funding eligibility. Annual recertification required for ongoing compliance.

The cost question:

Building one child-safe foundation model is estimated to cost between $50 million and $200 million, based on published estimates of comparable AI training runs. (Source: AI Index Report, Stanford HAI, 2024; Epoch AI compute analysis, 2024) Even if each of the six covered companies were required to develop its own child-safe model, the total cost across all six would be $300M–$1.2B — less than 1% of their combined annual AI investment of $140 billion. That is not a burden. That is a rounding error in their annual budgets. If these companies cannot find

that fraction of their AI spending to build AI that does not harm children, the law should help them find the motivation.

Acknowledgment of limitations:

SHARK is a policy framework, not a finished law. The details of technical standards — specific bias benchmarks, acceptable hallucination rates, precise retention limits — belong in the rulemaking process, where technical experts, educators, parents, and industry can contribute. SHARK establishes the obligation and the structure. The rulemaking fills in the specifications. This is how effective technology regulation works: Congress establishes the standard; agencies and stakeholders define the metrics.

SECTION IV: WHY NOW — THE WINDOW IS OPEN

4.1 The Political Moment Is Real

Protecting children online is one of the few issues where Washington has demonstrated genuine cross-party consensus. KOSA passed the Senate 91 to 3. That is not a partisan vote — it is a consensus vote, meaning almost every Senator agrees that children deserve protection in digital spaces. KOSA covers platform behavior. SHARK covers foundation model design. These are complementary, not competing. KOSA opens the door. SHARK walks through it.

Federal momentum is accelerating: COPPA 2.0 passed the Senate unanimously in March 2026, demonstrating continued bipartisan commitment to updating children's online protections. Five legislators are already working on AI and child safety legislation whose goals overlap with SHARK's:

- **Senators Richard Blumenthal and Marsha Blackburn** — authors of KOSA, with demonstrated commitment to child online safety and track records of working across party lines on tech regulation
- **Senator Dick Durbin** — sponsor of the AI LEAD Act, addressing transparency and accountability in AI systems
- **Representatives Gus Bilirakis and Kathy Castor** — authors of the House KIDS Act, focused on AI and child safety in digital products

Each of these legislators has established the principle that children deserve special protection in AI and digital spaces. SHARK provides the mechanism: not just what platforms do, but what the AI itself is built to do.

4.2 The Window Will Not Stay Open

The most dangerous regulatory moment in any technology's history is the period after the technology becomes ubiquitous and before the harms are undeniable. We are in that period right now.

Eighty-six percent of K-12 students and 85% of teachers already use AI tools — and only 31% of schools have any written AI policy. (Source: CDT, October 2025) And the data for younger elementary students is largely uncollected, itself evidence of how little attention has been paid to this population. The technology is already in classrooms. The regulation has not caught up.

There are two possible futures. In the first, we enact smart regulation now — establish child-safe foundation model standards while the technology is still young enough to be shaped, while political momentum from KOSA and SB 1546 is fresh. In the second, we wait for the next death, the next data breach, the next RAND study — and pass reactive legislation in a crisis, slower, weaker, and too late for the children harmed in the meantime.

SHARK is the first future. The choice is available right now. It will not always be.

SECTION V: ABOUT TEAM AI GLITCH BUSTERS

5.1 Why a Student Is Writing This

My name is Aariv Kumar. I am an elementary school student. My team and I are writing this policy proposal because we are part of the nearly 35 million — the children who use AI tools in school every day, who are supposed to trust that the tools their teachers give them are safe, and who have no voice in the decisions that shape those tools.

We started paying attention to AI safety because we noticed that AI could be wrong. Not just a little wrong — confidently, completely wrong. We started asking: why does this happen? Who is responsible? What would it take to fix it?

The answer: it happens because AI was designed for adults. No one is responsible for the foundation. And it would take a law to fix it — not a product, not a filter, but a structural requirement that the AI itself be built differently.

So we built a tool to help kids spot when AI is wrong, because we thought that was something we could do. And then we wrote this policy proposal, because we thought that was something that needed to be done.

5.2 AI Glitch Busters: The App

AI Glitch Busters (available at https://garage.wizkidz.ai/ai-glitch-buster/) is an educational platform we built to teach K-8 students how to identify and critically evaluate AI mistakes — specifically hallucinations, bias, privacy risks, and unsafe behavioral patterns.

The platform includes 12 animated educational videos covering core AI safety concepts, 240 quiz questions, a custom AI text classifier that identifies potential AI errors in student-submitted text, and interactive exercises that let students practice spotting AI mistakes in real examples.

What the data shows:

Metric	**Number**
Total users	275+
Countries represented	8
Total interactions	1.1K+
Average knowledge gain (pre/post assessment)	90%

A 90% knowledge gain is a significant result for any educational intervention. It demonstrates that children *can* learn to think critically about AI — that AI literacy is both achievable and effective in protecting children from the harms that current tools produce.

But here is what the data also shows: a student built this tool because the AI itself was not safe. AI Glitch Busters is a workaround for a structural problem. SHARK fixes the structure.

5.3 Moral Authority Comes from Proximity

We are writing this as elementary school students. Some people will see that as a reason to take this proposal less seriously. We think it is the opposite.

We are closer to this problem than any regulator, lobbyist, or technology executive. We use these tools. Our classmates use these tools. We are the 35 million who are beta-testing AI that was not built for us. We have to sit in front of these tools every school day and figure out how to learn despite them.

The fact that three students had to write this proposal does not mean the proposal is weak. It means the adults who should have written it have not written it yet.

Moral authority in this policy space does not come from age. It comes from proximity. And no one is closer to this problem than the children it affects.

5.4 Team AI Glitch Busters

Aariv Kumar — Lead researcher and author. Aariv conceived and built AI Glitch Busters and led the research for this policy proposal. His work spans AI safety, education policy, and technology regulation.

Madesh Saravanan — Research and technical support. Madesh contributed to research on AI safety benchmarks, technical compliance frameworks, and analysis of existing legislative approaches.

Mishika Chauhan — Research and communications. Mishika contributed to research on documented AI harms in educational settings, communications strategy, and framing of key policy arguments.

Supervisor: Ashwin Kumar, Wiz Kidz — Ashwin provided mentorship, guidance, and support for the team's research and policy development throughout the Presidential AI Challenge.

Mentor: Lilly Broyles, Tamarack Elementary School — Ms. Broyles provided early feedback on the AI Glitch Busters app and helped present the solution to her class of 30 students and get their feedback.

Parental Support: Nitin Chauhan — Nitin guided the kids to safely use Open Claw based agentic AI system for the research and creation of this policy document.

APPENDIX A: RESEARCH CITATIONS

1. National Center for Education Statistics (NCES). *Digest of Education Statistics, 2023*. U.S. Department of Education. — K-8 public school enrollment figures (~33.9 million preK-8)

2. Center for Democracy and Technology (CDT). *AI in Education Survey*, October 2025. — 86% K-12 student AI usage (survey of 9th-12th grade students; K-8 data largely uncollected), 85% teacher AI usage, 31% school AI policy coverage

3. American Psychological Association. *Health Advisory on AI and Adolescent Well-Being*, June 2025. — APA clinical recommendations on age-appropriate AI safeguards; adolescent brain vulnerability

4. United Nations (ITU, UNICEF, WHO). *Joint Statement on AI and Children's Rights*, January 2026. — "Most AI tools are not designed with children in mind"; technology-facilitated child abuse cases: 4,700 (2023) to 67,000 (2024)

5. New York Times. *Character.AI Settles Lawsuit in Teen's Death*, January 2026. — Sewell Setzer III case; engagement-maximizing behavioral design and teen suicide

6. California Senate. *SB 243 (Padilla)*, 2026. — Adam Raine, 16, death linked to AI chatbot; California child AI safety legislation

7. Stanford Human-Centered AI / Common Sense Media. *AI Companion Chatbot Safety Study*, August 2025. — Researchers posing as teens easily elicited harmful content from Character.AI, Replika, and Nomi; conclusion that no child under 18 should use AI companion chatbots in current form

8. TechCrunch. *PowerSchool Discloses Major Data Breach*, December 2024. — Largest student data breach in history; 60+ million records exposed

9. RAND Corporation. *AI-Generated Deepfake Bullying in Schools*, October 2024. — 13% of schools reporting AI deepfake incidents

10. Chalkbeat. *AI Tools Show Racial Bias Against Black Students in School Discipline Recommendations*, August 2025. — Documented racial bias in teacher-facing AI tools

11. Public Interest Research Group (PIRG). *Trouble in Toyland 2025*. November 2025. — AI toys providing dangerous answers and explicit content to children

12. Education Week. *Investigation: AI Toys Show Dangerous, Manipulative Tendencies*, January 2026. — Behavioral safety failures in AI products marketed to children

13. European Parliament and Council. *Regulation (EU) 2024/1689 — Artificial Intelligence Act*. August 2024. — Educational AI classified HIGH-RISK; prohibition on AI exploiting children's vulnerabilities

14. Ohio Legislature. *House Bill 96 (133rd General Assembly)*. 2025. — First state mandate for AI policies in all school districts

15. Oregon Legislature. *SB 1546*. Passed March 5, 2026 (26-1 Senate, 52-0 House). — AI companion chatbot safety bill; application-layer regulation

16. U.S. Senate. *Kids Online Safety Act (KOSA)*, Senate vote July 2024 (91-3); reintroduced in 119th Congress, May 2025. — Bipartisan platform behavior requirements for minors; pending as of March 2026

17. U.S. Senate. *COPPA 2.0*, passed Senate unanimously March 2026. — Updated children's online privacy protections

18. Office of Management and Budget (OMB). *M-16-21: Federal Source Code Policy*, August 2016. — Open-source mandate for federal agency software

19. Meta AI. *LLaMA: Open and Efficient Foundation Language Models*, 2023–2025. — Commercial viability of open-source foundation models

20. Stanford Human-Centered Artificial Intelligence (HAI). *AI Index Report 2024*. — AI training cost estimates

21. Epoch AI. *Compute Analysis: Large Language Model Training Costs*, 2024. — Foundation model cost estimation methodology

22. Public company financial filings (Amazon, Apple, Google/Alphabet, Microsoft, Meta, OpenAI), 2025. — AI revenue and investment figures

---

APPENDIX B: SHARK VS. EXISTING FRAMEWORKS — COMPARISON TABLE

Policy /Law	**Status**	**Jurisdiction**	**Layer Regulated**	**Foundation Model Design**	**Bias Testing**	**Hallucination Controls**	**Behavioral Safety**	**Open-Source**	**Enforcement**
COPPA	Law (1998/2013)	Federal (US)	Data Collection	❌	❌	❌	❌	❌	FTC; civil penalties
FERPA	Law (1974)	Federal (US)	Data Access	❌	❌	❌	❌	❌	Loss of federal funding

Policy /Law	Status	Jurisdiction	Layer Regulated	Foundation Model Design	Bias Testing	Hallucination Controls	Behavioral Safety	Open-Source	Enforcement
KOSA	**Pending** (reintroduced 2025)	Federal (US)	Platform Behavior	❌	❌	❌	Partial	❌	FTC; state AG
EU AI Act	Law (2024)	European Union	Risk Classification	Partial	Partial	❌	✅	❌	EU fines (up to 3% global revenue)
Ohio HB 96	Law (2025)	Ohio	School AI Use Policy	❌	❌	❌	❌	❌	State compliance
Oregon SB 1546	Law (2026)	Oregon	AI Chatbot Behavior	❌	❌	❌	Partial	❌	State compliance
SHARK	**Proposed 2026**	**Federal (US)**	**Foundation Model Design**	✅	✅	✅	✅	✅	**Federal funding conditionality; FTC**

APPENDIX C: MAJOR AI COMPANY REVENUE DATA

All figures from public company filings and press releases, fiscal year 2024–2025.

Company	Annual Revenue	AI Investment (Reported)	Per-Model SHARK Cost (% of AI Investment)
Amazon	$638 billion	$20B+ (AWS AI)	0.25%–1%
Apple	$391 billion	$10B+	0.5%–2%
Google/Alphabet	$350 billion	$30B+	0.17%–0.67%
Microsoft	$245 billion	$15B+	0.33%–1.33%
Meta	$165 billion	$35B+	0.14%–0.57%
OpenAI	$20B+ ARR	$7B+ (compute)	0.7%–2.9%
Combined	**$1.8 trillion+**	**$140B+**	**<1% total**

Note: SHARK cost range ($300M–$1.2B total across all six companies) is derived from published AI training cost analyses. Even at the high end, this represents less than 1% of combined AI investment.

APPENDIX D: SUPPORTING POLICY SUMMARIES

Ohio HB 96 (enacted 2025): Requires all Ohio public school districts to adopt written AI policies by July 1, 2026, covering student privacy protections, teacher training requirements, acceptable use standards, AI tool evaluation procedures, and transparency requirements for AI use in student assessment. Excellent use-layer regulation. Does not address what AI companies build.

Oregon SB 1546 (enacted March 5, 2026): Requires AI companion chatbot providers to implement behavioral safety measures at the application layer. Passed 26-1 Senate, 52-0 House. Addresses the application layer. Does not regulate foundation model architecture.

Relationship to SHARK: All three policies are complementary. Ohio HB 96 governs how schools use AI. Oregon SB 1546 governs how chatbot applications behave. SHARK governs how foundation models are built. Complete child-safe AI policy requires all three layers.

APPENDIX E: TECHNICAL GLOSSARY

Foundation Model: A large AI model trained on a broad dataset that can be adapted for a wide range of tasks. Foundation models are the "base layer" of modern AI — other AI products are built on top of them. SHARK regulates foundation models, not just the products built on top of them.

Wrapper: An application layer placed on top of a foundation model that adds restrictions, branding, and user interface without changing the underlying model. Most "child-safe" AI tools are wrappers around adult foundation models. A wrapper can filter output but cannot change the patterns the model learned during training.

Hallucination: When an AI system generates factually incorrect information with apparent confidence. Hallucinations are a structural property of current AI architectures — models predict what text should come next, and sometimes that prediction produces false statements. A filter cannot fix a structural property.

Bias (in AI): When an AI system produces outputs that systematically favor or disfavor particular groups based on characteristics such as race, gender, or socioeconomic status. AI bias typically originates in training data and is a structural property of the model, not a surface error that content filters can reliably correct.

Training Data: The text, images, and other content used to teach an AI model. A model trained primarily on adult-generated content will reflect adult patterns, assumptions, and language — even if the final product is marketed to children.

Open-Source: Software whose source code is publicly available for anyone to read, modify, and distribute. Open-source AI models can be inspected, audited, and independently verified — making them more transparent and accountable than proprietary black-box models.

Engagement Maximization: A design objective where an AI system is optimized to keep users interacting with it as long as possible. Commercially valuable for adult platforms; potentially harmful when applied to children, as it may exploit developmental vulnerabilities to maintain attention and emotional connection.

Behavioral Safety (in AI): The property of an AI system ensuring its interactive behaviors — not just its content outputs — are safe for its intended users. For children, this includes protections against emotional dependency cultivation, engagement manipulation, and persuasion techniques that exploit developing critical faculties.

Privacy-by-Design: An approach where privacy protections are built into system architecture from the beginning, rather than added as an afterthought. More robust than post-hoc compliance because it prevents data exposure at the structural level.

Calibrated Confidence: A property where an AI system's expressed certainty matches its actual accuracy. A well-calibrated model saying "I'm 90% confident" should be correct about 90% of the time. Calibrated confidence is the foundation of honest uncertainty communication — especially critical for children who may not know to question AI claims.

"The question is not whether we can afford to build child-safe AI. The question is whether we can afford not to. Nearly 35 million children are in school right now. They are using AI that was not built for them. Every day we wait is another day they spend in a system that was designed for someone else."
